

Fix the canonical polynomial datum r_d of degree < 8 in $\mathcal{D}_5 = \mathbb{C}[S]/(p_4)$.

Hasse slice of the two-axis closure order

$Z: \emptyset \longrightarrow \{1\}$ (upward)

ν increases to the right

$$(\nu, Z) \preceq (\nu', Z') \\ \iff \nu \leq \nu', \; Z \subseteq Z'$$

$$g_H \mid g_F \mid g_X, \quad g_X = E^a \prod_{i=1}^5 Q_i^{b_i}, \quad a + \sum_i b_i \leq 7 \quad (r_d \neq 0)$$

$E = S + 2, \; Q_i = S - \beta_i$. Splitting-field counts; the full-lift invariant uses the canonical representative.

Homogeneous spectrum • caps (1,1)

$g_H = \gcd(m_A, r_d)$
64 strata

Forcing memory • caps (3,1)

$g_F = \gcd(p_4, r_d)$
128 strata

Canonical lift • caps (4,2)

$g_X = \gcd(p_5, r_d)$
708 nonzero + zero
